(54) Title: METHODS AND COMPOSITIONS FOR IDENTIFYING OSTEOGENIC AGENTS

#### (57) Abstract

Methods and compositions for identifying osteogenic agents are disclosed, wherein a bone morphogenetic protein promoter is utilized in an assay system to modulate the production of an assayable product of a reporter gene.

# METHODS AND COMPOSITIONS FOR IDENTIFYING OSTEOGENIC AGENTS

# Technical Field

5

15

20

25

30

The present invention relates to assay techniques for identifying agents which modulate bone growth.

### Background of the Invention

Although there is a great deal of information available on the factors which influence the breakdown and resorption of bone, information on growth factors which stimulate the formation on growth factors which stimulate the formation of new bone is more limited. Investigators have searched for sources of such activities and have found that bone tissue itself is a storehouse for factors which have the capacity for stimulating bone cells. Thus, extracts of bovine tissue obtained from slaughterhouses contain not only structural proteins which are responsible for maintaining the structural integrity of bone, but also biologically active bone growth factors which can stimulate bone cells to proliferate. Among these latter factors are transforming growth factor  $\beta$ , the heparinbinding growth factors (acidic and basic fibroblast growth factor), the insulin-like growth factors (insulin-like growth factor I and insulin-like growth factor II) and a recently described family of proteins called bone morphogenetic proteins (BMPs). All of these growth factors have effects on other types of cells as well as on bone cells.

The BMPs are novel factors in the extended transforming growth factor  $\beta$  family. They were first identified in extracts of demineralized bone (Urist 1965, Wozney et al., 1988). Recombinant BMP-2 and BMP-4 can induce new bone formation when they are injected locally into the subcutaneous tissues of rats (Wozney 1992, Wozney & Rosen 1993). These factors are expressed by normal osteoblasts as they differentiate, and have been shown to stimulate osteoblast differentiation and bone nodule formation in vitro as well as bone formation in vivo (Harris et al., 1994). This latter property suggests potential usefulness as therapeutic agents in diseases which result in bone loss.

The cells which are responsible for forming bone are osteoblasts. As osteoblasts differentiate from precursors to mature bone-forming cells, they express and secrete a number of the structural proteins of the bone matrix including Type-1 collagen, osteocalcin, osteopontin and alkaline phosphates (Stein et al., 1990, Harris et al., 1994). They also

10

15

20

25

30

synthesize a number of growth regulatory peptides which are stored in the bone matrix and are presumably responsible for normal bone formation. These growth regulatory peptides include the BMPs (Harris et al, 1994). In studies of primary cultures of fetal rat calvarial osteoblasts, BMPs 1, 2, 3, 4, and 6 are expressed by cultured cells prior to the formation of mineralized bone nodules (Harris et al, 1994). Expression of the BMPs coincides with expression of alkaline phosphatase, osteocalcin and osteopontin.

Although the BMPs have powerful effects to stimulate bone formation in vitro and in vivo, there are disadvantages to their use as therapeutic agents to enhance bone healing. Receptors for the bone morphogenetic proteins have been identified in many tissues, and the BMPs themselves are expressed in a large variety of tissues in specific temporal and spatial patterns. This suggests that they may have effects on many tissues other than bone, potentially limiting their usefulness a therapeutic agents when administered systematically. Moreover, since they are peptides, they would have to be administered by injection. These disadvantages are severe limitations to the development of BMPs as therapeutic agents.

It is an object of the present invention to overcome the limitations inherent in known osteogenic agents by providing a method to identify potential drugs which would stimulate production of BMPs locally in bone.

# Prior Art

Sequence data on small fragments of the 5'-flanking region of the BMP-4 gene have been published (Chen et al, 1993, Kurihara et al, 1993), but the promoter has not been previously functionally identified or isolated.

# Disclosure of the Invention

A cell-based assay technique for identifying and evaluating compounds which stimulate the growth of bone is provided, comprising culturing a host cell line comprising an expression vector comprising a DNA sequence encoding a promoter region of at least one bone morphogenetic protein, operatively linked to a reporter gene encoding an assayable product under conditions which permit expression of said assayable product, contacting the cultured cell line with at least one compound suspected of possessing osteogenic activity, and identifying osteogenic agents by their ability to modulate the expression of the reporter gene and thereby increase the production of the assayable product.

10

15

20

25

This assay technique specifically identifies osteogenic agents which stimulate bone cells to produce bone growth factors in the bone morphogenetic protein family. These osteogenic agents display the capacity to increase the activity of the promoters of genes of members of the BMP family and other bone growth factors normally produced by e.g. bone cells.

Also provided in accordance with the present invention are isolated DNA sequences encoding a promoter region of at least one bone morphogenetic protein, and a system for identifying osteogenic agents comprising an expression vector comprising such promoter sequences operatively linked to a reporter gene encoding an assayable product, and means for detecting the assayable product produced a response to exposure to an osteogenic compound.

# Brief Description of the Drawings

Figure 1A graphically depicts a restriction enzyme map of mouse genomic BMP-4 and a diagram of two transcripts. The mouse BMP-4 gene transcription unit is -7kb and contains 2 coding exons (closed boxes) and 3 non-encoding exons, labeled exons 1A, 1B and 2. This 19kb clone has an -6kb 5' -flanking region and an -7kb 3' -flanking region. The diagram shows approximately 2.4kb of the 5' -flanking region, and a small region of the 3' -flanking region. The lower panel shows two alternative transcripts of BMP-4. Both have the same exons 2, 3 and 4 but a different exon 1. Transcript A has exon 1A and transcript B has exon 1B whose size was estimated according to RT-PCR and primer extension analysis in FRC cells;

Figure 1B depicts the DNA sequence of selected portions of mouse genomic BMP-4 (SEQ. ID NO. 1) and the predicted amino acid sequences of the identified coding exons (SEQ. ID NO. 2). The numbers on the right show the position of the nucleotide sequence and the bold numbers indicate the location of the amino acid sequence of the coding region. Most of the coding sequence is in exon 4. The end of the transcription unit was estimated based on a 1.8kb transcript. Primer 1 in exon 1A was used in RT-PCR analysis with Primer 3 in exon 3. Primer 2 in exon 1B was used in RT-PCR analysis with Primer B1 and B2 were used in primer extension reactions;

Figure 1C portrays the sequence of the BMP-4 exon 1A 5'-flanking region and potential response elements in the mouse BMP-4 1A promoter (SEQ. ID NO. 3). The

15

20

25

30

sequences of 2688 bp of the mouse BMP-4 gene are shown. Nucleotides are numbered on the left with +1 corresponding to the major transcription start site of the 1A promoter. The response elements of DR-1A Proximal and DR-1A Distal oligonucleotides are indicated. The other potential response DNA elements in the boxes are p53, RB (retinoblastoma), SP-1, AP-1, and AP-2. Primer A, indicated by the line above the DNA sequence at +114 to +96, was used for primer extension analysis of exon 1A-containing transcripts;

Figure 2 depicts the results of a primer extension assay. Total RNAs prepared from FRC cells (on the left frame) and mouse embryo 9.5 days (on the right) were used with primer A or the complement of primer 2. Two major extended fragments, 67 and 115 bp, indicated a lane A were obtained from primer A. Two 1B primers, primer B1 and primer B2, also gave negative results with both FRC and mouse embryo total RNA as template. Transcript B is not detectable with this assay. By RT-PCR, transcript B can be detected and quantified;

Figure 3A is a photographic representation of gel electrophoresis of 1A-3 and 1B-3 RT-PCR products of the BMP-4 gene. RT-PCR was performed with two pairs of primers using FRC cell poly A<sup>+</sup> mRNA as the template. The products were verified by the DNA sequence;

Figure 3B is a schematic diagram of spliced BMP-4 RT-PCR products with 1A and 1B exons in FRC cells. RT-PCR was performed with two pairs of primers using FRC cell poly A\* mRNA as the template. The diagram shows where the primers are located in the BMP-4 genomic DNA. RT-PCR product 1A-2-3 which contains exon 1A, exon 2 and the 5' region of exon 3, was produced with primer 1 and primer 3. Primer 2 and primer 3 generated two RT-PCR products with the exon 1B-2-3 pattern. The heterogeneity in size of exon 1B is indicated. The 1A promoter is predominantly utilized in bone cells:

Figure 4A provides a map of the BMP-4 1A 5'-flanking-CAT plasmid and promoter activity in FRC cells. The 2.6kb EcoR1 and Xba fragment, 1.3 kb Pst fragment, 0.5kb SphI and Pst fragment, and 0.25kb PCR fragment were inserted into pBLCAT3. The closed box indicates the non-coding exon 1A. The CAT box represents the CAT reporter gene. The values represent percentages of CAT activity expressed by pCAT-2.6 set at 100%. The values represent the average of four independent assays;

10

Figure 4B provides an autoradiogram of CAT assays using FRC cells transfected with BMP-4 1A 5'-flanking-CAT plasmids identified in Figure 4A;

Figure 5 portrays the nucleotid sequence of the mouse BMP-2 gene 5'-flanking region from -2736 to +139 (SEQ. ID NO. 4). The transcription start site is denoted by +1;

Figure 6A depicts an autoradiogram showing products of a primer extension assay for determination of the transcription start site of the BMP2 gene, separated on a 8% denaturing urea-polyacrylamide gel, in which Lane 1: Total RNA from fetal rat calvarial osteoblast cells, and Lane 2: Control lane with 10μg of yeast tRNA. All RNA samples were primed with a <sup>32</sup>p-labeled oligonucleotide from exon 1 to the mouser BMP2 gene, as indicated in Figure 6B. Lane M: <sup>32</sup>p-labeled MspI digested λ phage DNA, containing DNA fragments spanning from 623 bp to 15 bp (size marker);

Figure 6B provides a schematic representation of the primer extension assay. The primer used is a 18mer synthetic oligonucleotide, 5'-CCCGGCAAGTTCAAGAAG-3' (SEQ. ID NO. 5);

Figure 7 provides a diagram of selected BMP-2 promoter - luciferase reporter constructs. BMP-2 5'-flanking sequences are designated by hatched boxes (1) and luciferase cDNA is designated by the filled box (1). Base +114 denotes the 3' end of the BMP-2 gene in all the constructs;

Figure 8 displays the luciferase enzyme activity for the BMP-2 gene-LUC

constructs (shown in Figure 7) transfected in primary fetal rat calvarial osteoblasts (A),

HeLa cells (B) and ROS 17/2.8 osteoblasts (C). The luciferase activity has been normalized to β-galactosidase activity in the cell lysates;

Figure 9A-F depicts the DNA sequence of the mouse BMP-2 promoter and gene (SEQ. ID NO. 6); and

Figure 10A-D depicts the DNA sequence of the mouse BMP-4 promoter and gene (SEQ. ID NO. 7).

Figure 11 depicts the resequencing of the BMP-2 5' flanking region.

Detailed Description of the Preferred Embodiments

A cell-based assay technique for identifying and evaluating compounds which stimulate the growth of bone is provided, comprising culturing a host cell line comprising an expression vector comprising a DNA sequence encoding a promoter region of at least one bone morphogenetic protein operatively linked to a reporter gene encoding an assayable product under conditions which permit expression of said assayable product, contacting the cultured cell line with at least one compound suspected of possessing osteogenic activity, and identifying osteogenic agents by their ability to modulate the expression of the reporter gene and thereby increase the production of the assayable product.

10

15

20

25

30

The present invention is distinguished from other techniques for identifying boneactive compounds, as it specifically identifies chemical compounds, agents, factors or other
substances which stimulate bone cells to produce the bone growth factors in the bone
morphogenetic protein (BMP) family (hereinafter "osteogenic agents"). These osteogenic
agents are identified by their capacity to increase the activity of the promoters of genes of
members of the BMP family and other bone growth factors which are normally produced
by bone cells, and other cells including cartilage cells, tumor cells and prostatic cells. When
patients are treated with such chemical compounds, the relevant BMP will be produced by
bone cells and then be available locally in bone to enhance bone growth or bone healing.
Such compounds identified by this assay technique will be used for the treatment of
osteoporosis, segmental bone defects, fracture repair, prosthesis fixation or any disease
associated with bone loss.

Compounds that inhibit bone morphogenetic protein expression in bone or cartilage may also be useful in clinical situations of excess bone formation which occurs in such diseases as osteoblastic metastases or osteosclerosis of any cause. Such compounds can also be identified in accordance with the present invention.

Also provided in accordance with the present invention are isolated DNA sequences encoding a promoter region of at least one bone morphogenetic protein, and a system for identifying osteogenic agents comprising an expression vector comprising such promoter sequences operatively linked to a reporter gene encoding an assayable product, and means for detecting the assayable product produced in response to exposure to an osteogenic compound.

The promoters of the genes for BMP-4 and BMP-2 are complex promoters which can be linked to reporter genes, such as e.g. the firefly luciferase gene. When the hybrid genes (for example, bone cell BMP-4 promoter or bone cell BMP-2 promoter and firefly luciferases, chloramphenical acetyl transferase (CAT) cDNAs, or cDNA's for other reporter genes such as  $\beta$ -galactosidase, green fluorescent protein, human growth hormone, alkaline phosphatase,  $\beta$ -glucuronidase, and the like) are transfected into bone cells, osteogenic agents which activate the BMP-4 or BMP-2 promoters can be identified by their capacity in vitro to increase luciferase activity in cell lysates after cell culture with the agent.

5

10

15

20

25

30

Sequence data on small fragments of the 5'-flanking region of the BMP-4 gene have been published (Chen et al, 1993; Kurihara et al, 1993), but the promoter has not been previously identified or isolated, and methods for regulating transcription have not been shown. The present invention isolates the promoters for the BMP genes and utilizes these promoters in cultured bone cells so that agents could be identified which specifically increase BMP-2 or BMP-4 production locally in bone. Since it is known that the BMPs are produced by bone cells, a method for enhancing their production specifically in bone should avoid systemic toxicity. This benefit is obtained by utilizing the unique tissue specific promoters for the BMPs which are provided herein, and then using these gene promoters to identify agents which enhance their activity in bone cells.

By utilizing the disclosure provided herein, other promoters can be obtained from additional bone morphogenetic proteins such as BMP-3, BMP-5, BMP-6, and BMP-7, to provide comparable benefits to the promoters herein specifically described.

In addition, the present invention contemplates the use of promoters from additional growth factors in osteoblastic cells. Included are additional bone morphogenetic proteins, as well as fibroblast growth factors (e.g. FGF-1, FGF-2, and FGF-7), transforming growth factors  $\beta$ -1,  $\beta$ -2, and  $\beta$ -3, insulin-like growth factor-1, insulin-like growth factor-2, platelet-derived growth factor, and the like. Such promoters will readily be utilized in the present invention to provide comparable benefits.

The cells which can be utilized in the present invention include primary cultures of fetal rat calvarial osteoblasts, established bone cell lines available commercially (MC3T3-E1 cells, MG-63 cells, U2OS cells, UMR106 cells, ROS 17/2.8 cells, SaOS2 cells, and the like

as provided in the catal g from the American Type Culture Collection (ATCC)), and bone cell lines established from transgenic mice, as well as other cell lines capable of serving as hosts for the present vectors and systems. In addition, a number of tumor cell lines also express BMPs, including the prostate cancer cell lines PC3, LNCAP, and DUI145, as well as the human cancer cell line HeLa. Thus, any of a number of cell lines will find use in the present invention and the choice of an appropriate cell line will be a matter of choice for a particular embodiment.

The following examples serve to illustrate certain preferred embodiments and aspects of the present invention and are not to be construed as limiting the scope thereof.

### **EXPERIMENTAL**

In the experimental disclosure which follows, the following abbreviations apply: eq (equivalents); M (Molar); mM (millimolar);  $\mu$ M (micromolar); N (Normal); mol (moles); mmol (millimoles);  $\mu$ mol (micromoles); nmol (nanomoles); kg (kilograms); gm (grams); mg (milligrams);  $\mu$ g (micrograms); ng (nanograms); L (liters); ml (milliliters);  $\mu$ l (microliters); vol (volumes); and °C (degrees Centigrade).

# Example 1: DESCRIPTION AND CHARACTERIZATION OF MURINE BMP-4 GENE PROMOTER

20 (a) Library Screening, Cloning and Sequencing of Gene

A mouse genomic lambda fix II spleen library (Stratagene, La Jolla, CA) was screened with a mouse embryo BMP-4 cDNA kindly provided by Dr. B.L.M. Hogan (Vanderbilt University School of Medicine, Nashville, TN). The probe was labeled with [α-32 P]dCTP using a random-primer labeling kit from Boehringer-Mannheim (Indianapolis, IN). Plaque lift filters were hybridized overnight in 6X SSC, 5X Denhardt's. 0.5% SDS containing 200μg/ml sonicated salmon sperm DNA, 10μg/ml Poly A and 10μg/ml t-RNA at 68° C. The filters were washed at 55° C for 20 min, twice in 2X SSC, 0.1% SDS buffer, once in 0.5X SSC, 0.1% SDS. The isolated phage DNA clones were analyzed according to standard procedures (Sambrook *et al.*, 1989).

Fragments from positive clones were subcloned into pBluescrpt vectors (Stratagene, La Jolla, CA) and sequenced in both directions using the Sequenase SUBSTITUTE SHEET (RULE 26)

dideoxynucleotide chain termination sequencing kit (U.S. Biochemical Corp., Cleveland, OH).

Three clones were isolated from 2x10<sup>6</sup> plaques of mouse spleen 129 genomic library using full length coding region mouse embryo BMP-4 cDNA probe (B. Hogan, Vanderbilt University, Nashville, TN). One 19kb clone contained 5 exons and 6kb 5'-flanking region and a 7kb 3'-flanking region, as shown in Figure 1A. The 7kb transcription unit and the 5'-flanking region of the mouse BMP-4 gene were sequenced (Figure 10).

The nucleotide sequence of selected portions of mouse BMP-4 and the deduced amino acid sequence of the coding exons (408 residues; SEQ. ID NO. 2) is shown in Figure 1B. Primers used in the RT-PCR experiments described below are indicated in this Figure.

10

15

20

25

30

Figure 1C shows the DNA sequence of 2372bp of the 5'-flanking region and the candidate DNA response elements upstream of exon 1A. Primers used in primer extensions are also shown in Figures 1B and 1C.

(b) Primer Extension Mapping of the Transcriptional Start-Site of the Mouse BMP-4
Gene

The transcriptional start-sites were mapped by primer extension using the synthetic oligonucleotide primer A 5'-CGGATGCCGAACTCACCTA-3' (SEQ. ID NO. 8), corresponding to the complement of nucleotides +114 to +96 in the exon 1A sequence and the oligonucleotide primer B1 5'-CTACAAACCCGAGAACAG-3' (SEQ. ID NO. 9), corresponding to the complement of nucleotides +30 to +13 of the exon 1B sequence. Total RNA from fetal rat calvarial (FRC) cells and 9.5 day mouse embryo (gift of B. Hogan, Vanderbilt University) was used with both primers. The primer extension assay was carried out using the primer extension kit from Promega (Madison, WI). The annealing reactions were, however, carried out at 60°C in a water bath for 1 hr. The products were then electrophoresed on 8% denaturing-urea polyacrylamide gels and autoradiographed.

One additional oligonucleotide primer B2 5'-CCCGGCACGAAAGGAGAC-3' (SEQ. ID NO. 10), corresponding to the complement of nucleotide sequence +69 to +52 of exon 1B, was also utilized in primer extension reactions with FRC and mouse embryo RNAs.

1. Evidence for utilization of two alternate exon 1 sequences for the BMP-4 gene.

Several BMP-4 cDNAs were sequenced from prostate cancer cell in PC-3 and from primary FRC cells. Four independent FRC cell BMP-4 cDNAs all contained exon 1A. However, the human prostate carcinoma cell line (PC-3) cDNA contained an apparently unique exon 1B sequence spliced to exon 2 (Chem et al, 1993). A doubt-stranded oligonucleotide roble (70bp) to exon 1B was synthesized based on the human PC-3 exon 1B sequence. This exon 1B probe was then used to identify the exon 1B region in the mouse genomic BMP-4 clone. The candidate exon 1B is 1696bp downstream from the 3' end of exon 1A.

# 2. Primer extension analysis

5

10

15

20

30

Primer extension analysis was performed to map the mouse BMP-4 gene transcription start sites. Primer A, an oligonucleotide from exon 1A, was used and two oligonucleotides from exon 1B. Total RNA was utilized both from mouse embryo and FRC cells. As shown in Figure 2, a major extended fragment from primer A was obtained in both mouse embryo and FRC cell total RNAs, which migrates at 115bp. The extended 5'-end of the 115bp fragment represents the major transcription start site for 1A-containing transcripts. The site of this 5' non-coding exon 1A is 306bp. A major extended fragment from the complement of primer B1 (exon 1B) was not detected using both mouse embryo and FRC cell total RNAs. One other primer from exon 1B also gave negative results, suggesting that in 9.5 day mouse embryo and FRC cells, the exon 1B-containing transcripts were not detectable, which suggests that transcripts containing exon 1B are less abundant in these cells and tissues than transcripts containing exon 1A. All primer extensions were carried out after annealing of primers at high stringency. Lower stringency annealing with 1B primers gave extended products not associated with BMP-4 mRNA.

25 (c) BMP-4 Gene 5 Flanking Region for Exon 1A and 1B Transcripts.

Four FRC BMP-4 cDNA were sequenced and found to contain exon 1A sequences spliced to exon 2. The human U20S BMP-4 cDNA sequence also contains exon 1A (Wozney et al, 1988). This suggests the BMP-4 gene sequences upstream or exon 1A are used primarily in bone cells.

To test whether the BMP-4 1B promoter is utilized at all in FRC cells, oligonucleotide primers were designed to ascertain whether spliced 1B-2-3 exon products

SUBSTITUTE SHEET (RULE 26)

10

15

and 1A-2-3 exon (control) products could be obtained by more sensitive RT-PCR technique using FRC poly (A<sup>+</sup>)-RNA. The 3' primer was in exon 3 (Figure 1B - Primer 3) and the 5' primers were either in exon 1A (primer 1) or exon 1B (primer 2).

The RT-PCR products were cloned and sequenced. A photograph and diagram of the products obtained are presented in Figure 3A and B. Both 1A-2-3 and 1B-2-3 products were obtained. The results indicate FRC osteoblasts produce transcripts with either 1A exon or a 1B exon, but not both. This suggests that the intron region between 1A and 1B exons could contain regulatory response elements under certain conditions. Of the 1B-2-3 RT-PCR products obtained from FRC osteoblasts, two products were obtained with different 3' splice sites for the exon 1B. By comparison with the genomic DNA, both 3' ends of the two exon 1Bs have reasonable 5' splice consensus sequences, consistent with an alternate splicing pattern obtained for the 1B-2-3 RT-FCR products. Most importantly, no 1A-1B-2-3 RT-PCR splice products of the BMP-4 gene were obtained. Thus, 1B does not appear to be alternatively spliced 5'-non-encoding exon. By quantitative RT-PCR, it was shown that 1A transcripts are 10 to 15X more abundant in primary bone cells.

The technique of performing RT-PCR will be described. First-strand cDNA was synthesized from 1µg FRC cell poly (A+)-RNA with an 18mer dT primer using Superscript™ reverse transcriptase (Gibco BRL) in a total volume of 20µ1. The cDNA was then used as a template for PCR with two sets of synthesized primers. As shown in Figure 1B, primer 1 (5'-GAAGGCAAGAGCGCGAGG-3) (SEQ. ID No. 11), 20 corresponding to a 3' region of exon 1A and primer 3 (5'-CCGGTCTCAGGTATCA-3') (SEQ. ID No. 12), corresponding to a 5' region of exon 3 were used to generate exon 1A-2-3 spliced PCR product. Primer 2 (5'-CAGGCGGAAAGCTGTTC-3') (SEQ. ID NO. 13), corresponding to a 3' region (+2 to +18) of exon 1B, and primer 3 were used to generate exon 1B-2-3 spliced PCR products. GeneAmp PCR kit was used according to the 25 manufacturer's procedure (Perkin-Elmer/Cetus, Norwalk, CT). Each cycle consisted of a denaturation step (94°C for 1 min), an annealing step (59°C for 2 min) and an elongation step (72°C for 1 min). The PCR products were analysed by agarose gel electrophoresis for size determination. The products were subcloned into pCR II vector using TA cloning kit (InVitrogen, San Diego, CA). The inserts were sequenced in both directions with a 30 sequencing kit from U.S. Biochemical (Cleveland, OH).

20

25

30

Northern analysis demonstrated that the single 1.8kb BMP-4 transcript detected in FRC cells during bone cell differentiation hybridizes to both a pure 1A exon probe and a 2-4 exons probe. The ratio of the 1A to 2-4 signal is constant through the changing levels of BMP-4 expression during differentiation. Using a 1B exon probe no detectable hybridization to the BMP-4 exon 2-4 1.8kb signal was observed. This again indicates that 1A containing transcripts predominate in bone cells, although 1B transcripts can be detected by the more sensitive PCR method. By quantitative PCR it was shown that 1A transcripts are 10-15X more abundant than 1B in FRC cells.

(d) BMP-4 Promoter 1A Plasmid Construction and Transfection, and Detection of
Promoter Activity in Osteoblasts.

Three BMP-4 1A promoter/plasmids were constructed by excising fragments from the 5' flanking region of the mouse BMP-4 gene and cloning into pBL3CAT expression vectors (Luckow and Schutz, 1987). The pCAT-2.6 plasmid was the pBLCAT3 vector with a 2.6kb EcoR1 and Xba I fragment (-2372/+258) of the BMP-4 gene. The pCAT-1.3 plasmid was similarly generated from a 1.3kb Pst fragment (-1144/+212). The pCAT-0.5 plasmid was made from a 0.5kb SphI and Pst fragment (-260/+212). Both the pCAT-1.3 and the pCAT-0.5 plasmids have 212bp of exon 1A non-coding region. An additional promoter/plasmid was created from a PCR amplified product, corresponding to the 240bp sequence between nucleotides -25 and +212, and referred to as the pCAT-0.24. The amplified fragment was first cloned into pCR II vector using TA cloning kit (InVitrogen, San Diego, CA) and then the fragment was released with Hind III and Xho I, and relegated into pBL3CAT. Correct orientation of all inserts with respect to the CAT vector was verified by DNA sequencing.

The cells used for transient transfection studies were isolated from 19 day-old fetal rat calvariae by sequential digestion with trypsin and collagenase, as described by Bellows et al, (1986) and Harris et al, (1994). In brief, the calvarial bone were surgically removed and cleaned by washing in  $\alpha$  minimal essential media ( $\alpha$ MEM) containing 10% V/V fetal calf serum (FCS) and antibiotics. The bones were minced with scissors and were transferred to 35mm tissue culture dish containing 5ml of sterile bacterial collagenase (0.1%) and trypsin l (0.05%). This was then incubated at 37°C for 20 min. The cells released at this time were collected and immediately mixed with an equal volume of FCS to inactivate trypsin. This procedure is repeated 6 times to release cells at 20 min intervals.

Cells released from 3rd, 4th, 5th and 6th digestion (enriched for osteoblasts) were combined and the cells are collected by centrifugation at 40 Xg for 5 min. The cells were then plated in aMEM containing 10% FCS and antibiotics and were grown to confluency (2-3 days). At this stage the cells were plated for transfection in 60mm tissue culture dishes at a cell density of 5 x 10<sup>5</sup> cells per dish. These primary osteoblast cultures are capable of self-organizing into bone-like structure in prolonged cultures (Bellows et al, 1986; Harris et al, 1994). HeLa, ROS 17/2.8, and CV-1 cells were purchased from the ATCC.

The isolated FRC cells, enriched for the osteoblast phenotype, were used as recipient cells for transient transfection assays. BMP-4 mRNA is modulated in these cells in a transient fashion during prolonged cultured (Harris et al, 1994b). The technique of electroporation was used for DNA transfection (Potter, 1988; van den Hoff et al, 1992). After electroporation, the cells were divided into aliquots, replated in 100mm diameter culture dishes and cultured for 48 hours in modified Eagle's minimal essential media (MEM, GIBCO, Grand Island, NY) with 10% fetal calf serum (FCS). The extracts were assayed for CAT actively according to the method described by Gorman (1988) and CAT activity was normalized by β-galactosidase assay according to the method of Rouet et al (1992).

After 48 hrs of transfections with various BMP-4-CAT reporter gene plasmid

constructs, the cells were harvested and the CAT activity was determined. As indicated in
Figure 4A and 4B, pCAT-0.24 plasmid (-25/+212) has little CAT activity. This plasmid

contains -25 to +212 of the 5' non-coding exon 1A and was 3-fold lower that the parent

pBL3CAT plasmid. The pCAT-0.5 (-260/+212), pCAT-1,3 (-1144/+212), and pCAT-2.6

(-2372/+258) showed progressive increasing CAT activity when transfected into FRC cells.

These data are shown in Figure 4B. With pCAT-0.5 (-260/+212) there is a 10-fold

increase in CAT activity relative to pCAT-0.24 (-25/+212). pCAT-1.3 (-1144/+212)

shows a further 6-fold increase and pCAT-2.6 (-2372/+258) shows further 2-fold change

over pCAT-1.3 (-1144/+212). Thus the net increase in CAT activity between the pCAT
0.24 (+257/+212) and the pCAT-2.6 (-2372/+258) in FRC cells is approximately 100-fold.

15

Example 2: DESCRIPTION AND CHARACTERIZATION OF MURINE BMP-2 GENE PROMOTER

SUBSTITUTE SHEET (RULE 26)

### (a) Cloning of Mouse BMP-2 Genomic DNA.

Genomic clones of the mouse BMP-2 gene were isolated in order to determine the transcriptional regulation of the BMP-2 gene in primary osteoblasts. 5 x 10<sup>6</sup> plaques were screened from a mouse genomic library, B6/CBA, (purchased from Stratagene, San Diego, CA) using BMP-2 cDNA as probe. The BMP-2 cDNA clone was isolated from a cDNA library of PC3 prostate cancer cells (Harris et al, 1994). The human BMP-2 probe was a 1.1kb Smal fragment containing most of the coding region.

PCT/US96/08197

The BmP-2 genomic clones were sequenced by dideoxy chain termination method (Sanger et al, 1977), using deoxyadenosine 5'-[α[<sup>35</sup>S]thio] triphosphate and Sequenase

(United States Biochemical, Cleveland, OH). All fragments were sequenced at least twice and overlaps were established using the appropriate oligonucleotic primer. Primers were prepared on an Applied Biosystems Model 392 DNA Synthesizer. Approximately 16kb of one of these BMP-2 clones was completely sequenced (Figure 9). Analysis of this sequence showed that the mouse BMP-2 gene contains one encoding and two coding exons (Feng et al, 1994). Analysis of the 5' flanking sequence showed that the BMP-2 gene does not contain typical TATA oar CAAT boxes. However, a number of putative response elements and transcription factor recognition sequences were identified upstream of exon 1 (Figure 5). The 5'-flanking region is GC rich with several SP-1, AP-1 P53, E-box, homeobox, and AP-2 candidate DNA binding elements.

20 (b) Analysis of Transcription Start Site for BMP-2 Gene.

25

The transcription start sites for the BMP-2 gene were identified using the primer extension technique. Primer extension was carried out as described (Hall et al., 1993). The primer used was a <sup>32</sup>p-labeled 18 mer oligonucleotide 5'-CCCGGCAATTCAAGAAG-3' (SEQ. ID NO> 5). Total RNA obtained from primary fetal rat calvarial osteoblasts, was used for the primer extension. The results were shown in Figure 6. The major extension product was 68bp and was used to estimate the major transportation start site (+1, Figure 5). These results were confirmed by Rnase protection assays.

- (c) Identification of BMP-2 Promoter and Enhancer

  Activity Using Luciferase (LUC) Reporter Gene Constructs.
- The BMP-2-LUC constructs (Figure 7) were designed to contain variable 5' boundaries from BMP-2 5'-flanking sequences spanning the transcription start site (+1).

  SUBSTITUTE SHEET (RULE 26)

10

15

20

25

Each construct contained the 3' boundary at +114 9 in exon 1 (Figure 6). These constructs were individually transfected into primary cultures of fetal rat calvarial osteoblasts, ROS 17/2.8 osteosarcoma cells, HeLa cells, and CV-1 cells by the calcium-phosphate precipitation technique and the promoter activity for each of these constructs was assayed 24 hrs following transfection by measuring the luciferase enzyme activity for each individual cell lysate. The LUC (luciferase enzyme assay) technique is described below under (f). Plasmid psvβGal was co-transfected with each plasmid construct to normalize for the transfection efficiency in each sample. The experiments were repeated at least five times in independent fetal rat calvarial cultures, with each assay done in triplicate. The mean values from a representative experiment are shown in Figure 8.

(d) Isolation of Primary Fetal Rat Calvarial Osteoblasts for Functional Studies of BMP-2 Gene Promoter.

The cells used for transient transfection studies were isolated from 19 day-old fetal rat calvariae by sequential digestion with trypsin and collagenase, as described by Bellow et al., (1986) and Harris et al., (1994). In brief, the calvarial bone were surgically removed and cleaned by washing in a minimal essential media (aMEM) containing 10% V/V fetal calf serum (FCS) and antibiotics. The bones were minced with scissors and was transferred to 35 mm tissue culture dish containing 5 ml of sterile bacterial collagenase (0.1%) and trypsin (0.05%). This was then incubated at 37°C for 20 min. The cells released at this time were collected and immediately mixed with an equal volume of FCS to inactivate trypsin. This procedure was repeated 6 times to release cells at 20 min intervals. Cells released from 3rd, 4th, 5th and 6th digestion (enriched for osteoblasts) were combined and the cells were collected by centrifugation at 400 g for 5 min. The cells were then plated in aMEM containing 10% FCS and antibiotics and were grown to confluency (2-3 days). At this stage the cells were plated for transfection in 60 mm tissue culture dishes at a cell density of 5 x 10<sup>5</sup> cells per dish. These primary osteoblst cultures are capable f mineralized bone in prolonged cultures (Bellows et al, 1986; Harris et al, 1994). HeLa, ROS 17/2.8, and CV-1 cells were purchased from the ATCC.

# (e) Transient Transfection Assay.

For transient transfection assay, the primary osteoblast cells were plated at the above mentioned cell density 18-24 hrs prior to transfection. The transfection was carried out using a modified calcium-phosphate precipitation method (Graham & van der Eb 1973;

20

Frost & Williams 1978). The cells were incubated for 4 hrs. at 37°C with 500µl of a calcium phosphate precipitate of plasmid DNA containing 10µg of reporter plasmid construct and 1µg of pSVβGal (for normalization of transfection efficiency) in 0.15M CaCl<sub>2</sub> and Hepes buffered saline (21mM Hepes, 13.5mM NaCl, 5mM KCl, 0.7mM Na<sub>2</sub>HPO<sub>4</sub>, 5.5mM dextrose, pH 7.05-7.1). After the 4 hr. incubation period of cells with precipitate, the cells were subjected to a 2 min treatment of 15% glycerol in aMEM, followed by addition of fresh aMEM containing insulin, transferrin and selenium (ITS) (Upstate Biotechnology Lake Placid, NY). The cells were harvested 24 hrs post transfection.

# 10 (f) Luciferase and $\beta$ -galactosidase Assay.

Cells lysates were prepared and luciferase enzyme assay was carried out using assay protocols and the assay kit from Promega (Madison, WI). Routinely 20μ1 of cell lysate was mixed with 100μ1 of luciferase assay reagent (270μM coenzyme A, 470μM luciferin and 530μM ATP) and the luciferase activity was measured for 10 sec in a TURNER TD-20e luminometer. The values were normalized with respect to the β-galactosidase enzyme activity, obtained for each experimental sample

The β-galactosidase enzyme activity was measured in the cell lysate using a 96 well microtiter plate according to Rouet et al. (1992). 10-20μ1 cell lysate was added to 90-80μ1 β-galactosidase reaction buffer containing 88mM phosphate buffer, PH 7.3, 11mM KCL, 1mM MgCl<sub>2</sub>, 55mM β mercaptoethanol, 4.4mM chlorophenol red β-D-galactopyranoside (Boehringer-Mannheim Corp., Indianapolis, IN). The reaction mixture was incubated at 37°C for 30-60 min, depending on transfection efficiency, and the samples were read with an ELISA plate reader at 600nm.

# (g) Plasmid Construction

The luciferase basic plasmid (pGL basic) was the vector used for all constructs (purchased from Promega, Madison, WI). Different lengths of DNA fragments from the BmP-2 5'-flanking region were cloned at the multiple cloning sites of this plasmid, which is upstream of the firefly luciferase cDNA. The BMP-2 DNA fragments were isolated either by using available restriction enzyme sites (constructs -196/+114, -876/+114, -1995/+114, -2483/+114, and -2736/+114) or by polymerase chain reaction using specific oligonucleotide primers (constructs -23/+114, -123/+114 and +29/+114.

The minimal promoter activity for the BMP-2 gene was identified in the shortest construct containing 23bp upstream of the transcription start site (-23/+114). No luciferase activity was noted in the construct and did not include the transcription start site (+29/+114). Two other constructs containing increasing lengths of 5' sequences up to -196bp showed reproducible decreases in promoter activity in fetal rat calvarial osteoblasts and HeLa cells (Figure 8). The -876/+114 construct showed a 5-fold increase in activity in HeLa cells. The -1995/+114, -2483/+114 and -2736/+114 constructs showed decreased promoter activity when compared to the -876/+114 construct only in HeLa cells (Figure 8).

PCT/US96/08197

In the primary fetal rat calvarial osteoblasts, the 2.6kb construct (-2483/+114) demonstrated a 2-3-fold increase in luciferase activity over that of the -1995/+114 construct (Figure 8). These results suggest that one or more positive response regions are present between -196 and -1995 and that the DNA sequence between -1995 and -2483bp was other positive regulatory elements that could modulate BMP-2 transcription. The largest 2.9kb construct (-2836/+114) repeatedly demonstrated a 20-50% decrease in promoter activity compared to the -2483/+114 construct, in these primary fetal rat calvarial osteoblasts (Figure 8).

In ROS 17/2.8 osteosarcoma cells, the BMP-2 promoter activity was consistently higher than either the primary fetal rat calvarial osteoblasts or HeLa cells (Figure 8). All of the deletion constructs showed similar promoter activity in ROS 17/2.8 osteosrcoma cells. The transformed state in ROS 17/2.8 cells may be responsible for the marked expression of the BMP-2 gene. ROS 17/2.8 cells represent a well differentiated osteosrcoma and they produce high levels of BMP-2 mRNA. They form tumors in nude mice with bone-like material in the tumor (Majeska et al, 1978; Majeska et al, 1980).

### (h) Specificity of the BMP-2 Promoter.

10

15

To analyze the activity of the BMP-2 promoter in cell types not expressing BMP-2 mRNA, BMP-2 promoter constructs were transfected into CV-1 cells (monkey kidney cells). The BMP-2 promoter activity was found to be very low for all constructs. This suggests that this region of the BMP-2 promoter is functional only in cells such as primary fetal rat calvarial osteoblasts, HeLa and ROS 17/2.8 that express endogenous BMP-2 mRNA (Anderson & Coulter 1968). CV-1 cells do not express BMP-2 mRNA. The

10

15

20

25

30

BMP-2 promoter is likely active in other cell types that express BMP-2, such as prostate cells and chondrocytes, although regulation of transcription may be different in these cells.

Example 3: USE OF PLASMID CONSTRUCTS CONTAINING BMP PROMOTERS WITH REPORTER GENES TO IDENTIFY OSTEOGENIC AGENTS

Plasmid constructs containing BMP promoters with reporter genes have been transfected into osteoblastic cells. The cells which have been utilized include primary cultures of fetal rat calvarial osteoblasts, cell lines obtained as gifts or commercially (MC3T3-E12 cells, MG-63 cells, U2OS cells, UMR106 cells, ROS 17/2.8 cells, Sa)S2 cells, and the like as provided in the catalog from the ATCC) and bone and cartilage cell lines established from transgenic mice. The bone cells are transfected transiently or stably with the plasmid constructs, exposed to the chemical compound, agent or factor to be tested for 48 hours, and then luciferase or CAT activity is measure in the cell lysates.

Regulation of expression of the growth factor is assessed by culturing bone cells in  $\alpha$ MEM medium with 10% fetal calf serum and 1% penicillin/streptomycin and 1% glutamine. The cells are placed in microtiter plates at a cell density of  $5\times10^3$  cells /100 $\mu$ 1/well. The cells are allowed to adhere and then incubated at 37°C at 5% CO<sub>2</sub> for 24 hours and then the media is removed and replaced with 50 $\mu$ 1  $\alpha$ MEM and 4% fetal calf serum, 50 $\mu$ 1 aliquots containing the compound or factor to be tested in 0.1% BSA solution is added to each well. The final volume is 100 $\mu$ 1 and the final serum concentration is 2% fetal calf serum. Recombinant rat BMP-2 expressed in Chinese hamster ovarian cells is used as a positive control.

The treated cells are incubated at 37°C at 5% CO<sub>2</sub> for 48 hours. The media is then removed and the cells are rinsed 3 times with phosphate buffered saline (PBS). Excess PBS is removed from the wells and 100µ1 of cell culture lysing reagent (Promega #E153A) is added to each well. After 10 minutes, 10µ1 of the cell lysate is added to a 96-well white luminometric plate (Dynatech Labs #07100) containing 100µ1 luciferase assay buffer with substrate (Promega #E152A). The luciferase activity is read using a Dynatech ML2250 automated 96-well luminometer. The data is expressed as either picograms of luciferase activity per well or picograms of luciferase per µg protein.

15

20

25

30

Example 4: DEMONSTRATION THAT BONE CELLS TRANSFECTED WITH BMP PROMOTERS CAN BE USED TO SCREEN FOR OSTEOGENIC AGENTS

To demonstrate that the present invention is useful in evaluating potential osteogenic agents, a random array of chemical compounds from a chemical library obtained 5 commercially was screened. It was found that approximately 1 in 100 such compounds screened produces a positive response in the present assay system compared with the positive control, recombinant BMP-2, which is known to enhance BMP-2 transcription. Compounds identified from the random library were subjected to detailed dose-response curves, to demonstrate that they enhance BMP messenger RNA expression, and that they enhance other biological effects in vitro, such as expression of structural proteins including osteocalcin, osteopontin and alkaline phosphase, and enhance bone nodule formation in prolonged primary cultures of calvarial rodent osteoblasts.

Compounds identified in this way can be tested for their capacity to stimulate bone formation in vitro in mice. To demonstrate this, the compound can be injected locally into subcutaneous tissue over the calvarium of normal mice and then the bone changes are followed histologically. It has been found that certain compounds identified by the presentinvention stimulate the formation of new bone in this in vivo assay system.

The effects of compounds are tested in ICR Swiss mice, aged 4-6 weeks and weighing 13-26g. The compound at 20mg/kg or vehicle along (100µl of 5% DMSO and phosphate-buffered 0.9% saline) are injected three times daily for 7 days. The injections are given into the subcutaneous tissues overlying the right side of the calvaria of five mice in each treatment group in each experiment.

Mice are killed by either inhalation on day 14, i.e. 7 days after the last injection of compound. After fixation in 10% phosphate-buffered formalin, the calvariae are examined. The occipital bone is removed by cutting immediately behind and parallel to the lambdoid suture, and the frontal bone is removed by cutting anterior to the coronal suture using a scalpel blade. The bones are then bisected through the coronal plane and the 3- to 4mm strips of bone are decalcified in 14% EDTA, dehydrated in graded alcohols, and embedded in paraffin. Four 3 µm thick nonconsecutive step sections are cut from each specimen and stained using hematoxylin and eosin.

Two representative sections from the posterior calvarial strips are used. Histological measurements are carried out using a digitizing tablet and the Osteomeasure SUBSTITUTE SHEET (RULE 26)

10

15

20

image analysis system (Osteometrics Inc., Atlanta, GA) on the injected and noninjected sides of the calvariae in a standard length of bone between the sagittal suture and the muscle insertion of the lateral border of each bone. Measurements consist of (1) Total bone area (i.e., bone and marrow between inner and outer periosteal surfaces); (2) Area of new woven bone formed on the outer calvarial surface; (3) The extent of osteoblast lined surface on the outer calvarial surface; (4) The area of the outer periosteum; and (5) The length of calvarial surface. From these measurements, the mean width of new bone and periosteum and the percentage of surface lined by osteoblasts on the outer calvarial surface, can be determined.

By reference to the above disclosure and examples, it is seen that the present invention provides a new cell-based assay for identifying and evaluating compounds which stimulate the growth of bone. Also provided in accordance with the present invention are promoter regions of bone morphogenetic protein genes, and a system for identifying osteogenic agents utilizing such promoters operatively linked to reporter genes in expression vectors.

The present invention provides the means to specifically identify osteogenic agents which stimulate bone cells to produce bone growth factors in the bone morphogenetic protein family. These osteogenic agents are shown to be useful to increase the activity of the promoters of genes of members of the BMP family and other bone growth factors normally produced by bone cells.

# Example 5: RESEQUENCING OF THE BMP-2 5 FLANKING REGION

The BMP-2 5' flanking region described in Example 2 was resequenced. The nucleotide sequence of the 5' flanking region of the mouse BMP-2 gene is provided in Figure 11. The sequence information in Figure 11 corrects sequencing errors that are present in Figures 5 and 9. The nucleotide sequence of Figure 11 replaces bases -2736 to +119 provided in Figure 5 and bases 1 to 2855 provided in Figure 9. The non-nucleotide sequence information provided in Figure 5 is applicable to the corresponding bases in Figure 11 where such bases are present.

All publications and patent applications cited in this specification are herein incorporated by reference as if each individual publication or patent application are [is] specifically and individually indicated to be incorporated by reference.

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity and understanding, it will be apparent to those of ordinary skill in the art in light of the teaching of this invention that certain changes and modifications may be made thereto without departing from the spirit or scope of the appended claims.

### (2) INFORMATION FOR SEQ ID NO:7:

### (i) SEQUENCE CHARACTERISTICS:

- (A) LENGTH: 9299 base pairs
- (B) TYPE: nucleic acid
- (C) STRANDEDNESS: single
- (D) TOPOLOGY: linear

#### (ii) MOLECULE TYPE: DNA (genomic)

### (xi) SEQUENCE DESCRIPTION: SEQ ID NO:7:

## **Claims**

- 1. A system for identifying osteogenic agents comprising a recombinant host cell modified to contain an expression sequence comprising a promoter derived from a gene encoding a bone morphogenic protein operatively linked to a reporter gene encoding an assayable product.
- 2. The system of claim 1 wherein said bone morphogenic protein is selected from the group consisting of the BMP-2 and BMP-4 proteins.
- 3. The system of claim 1 or 2 wherein said reporter gene comprises a gene encoding the production of an assayable product selected from the group consisting of firefly luciferase, chloramphenical acetyl transferase,  $\beta$ -galactosidase, green fluorescent protein, human growth hormone, alkaline phosphatase and  $\beta$ -glucuronidase.
- 4. The system of claim 3 wherein said reporter gene comprises a gene encoding the production of firefly luciferase.
- 5. A method for identifying an osteogenic compound comprising the steps of:

  culturing the cells of any of claim 1-4 under conditions which permit expression of
  said assayable product from said reporter gene;

contacting said cells with at least one candidate compound suspected of possessing osteogenic activity;

measuring the amount of assayable product produced in the presence of said candidate compound and comparing said amount to the amount of assayable product produced in the absence of said candidate compound; and

identifying, as an osteogenic compound, a candidate compound that enhances the amount of said assayable product when present.

- (2) INFORMATION FOR SEQ ID NO:12:
  - (i) SEQUENCE CHARACTERISTICS:
    - (A) LENGTH: 17 base pairs
    - (B) TYPE: nucleic acid
    - (C) STRANDEDNESS: single
    - (D) TOPOLOGY: linear
  - (ii) MOLECULE TYPE: cDNA
  - (xi) SEQUENCE DESCRIPTION: SEQ ID NO:12:

CCCGGTCTCA GGTATCA

17

- (2) INFORMATION FOR SEQ ID NO:13:
  - (i) SEQUENCE CHARACTERISTICS:
    - (A) LENGTH: 17 base pairs
    - (B) TYPE: nucleic acid
    - (C) STRANDEDNESS: single
    - (D) TOPOLOGY: linear
  - (ii) MOLECULE TYPE: cDNA
  - (xi) SEQUENCE DESCRIPTION: SEQ ID NO:13:

CAGGCCGAAA GCTGTTC

17

- 6. An isolated nucleic acid molecule comprising a nucleotide sequence encoding the promoter region of a gene encoding bone morphogenetic protein selected from the group consisting of the BMP-2 and BMP-4 proteins.
- 7. The nucleic acid molecule of claim 6 which corresponds to a nucleotide sequence selected from the group consisting of positions -2372 to +316 of the BMP-4 gene depicted in Figure 1C (SEQ ID NO:3), a portion thereof which encodes a biologically active promoter, the BMP-2 sequence depicted in Figure 11, and a portion thereof which encodes a biologically active promoter.
- 8. A recombinant expression vector comprising the nucleotide sequence of claim 6 or 7.
- 9. The recombinant expression vector of claim 8 wherein said nucleotide sequence is operatively linked to a reporter gene encoding an assayable product.
- 10. The recombinant expression vector of claim 9 wherein said reporter gene comprises a gene encoding the production of an assayable product selected from the group consisting of firefly luciferase, chloramphenical acetyl transferase, β-galactosidase, green fluorescent protein, human growth hormone, alkaline phosphatase or β-glucuronidase.

139
                         Homeobox 10 and 12 are identical at 8/8 sites, in an inverted
                          Orientation.
 Candidate
                          Homeobox 3, 4, 5, 9 should bind MSX1 and/or MSX2 with
Homeo Box | relatively high affinity.
Binding

## INTERNATIONAL SEARCH REPORT

International application No. PCT/US96/08197

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)
This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:
1. Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:
2. Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. X Claims Nos.: 5 because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).
Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)
This International Searching Authority found multiple inventions in this international application, as follows:
1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
*
4. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
Remark on Protest The additional search fees were accompanied by the applicant's protest.
No protest accompanied the payment of additional search fees.
